

PROOF2PAY AI - Idea & Business Canvas

Agentic Job Completion & Billing Readiness Platform

Hackathon Edition - 27 September 2026

Executive snapshot

Tagline: *Finish the job. Prove the job. Get paid.*

One-liner. PROOF2PAY AI helps B2B field-service teams turn a reported-complete job into an explainable, evidence-backed, human-approved billing-ready package.

Core thesis: A job can be finished in the field while still not being ready for billing.

1. Problem

Field-service completion evidence often arrives across different formats and moments: technician notes, photos, checklists, measurement results, work orders, service reports, customer acknowledgement, and handover documents. Before finance can safely proceed, operations may still need to determine whether the available proof satisfies the job's completion requirements.

The MVP focuses on three frictions:

1. **Evidence fragmentation** - proof is spread across notes, files, photos, and systems.
2. **Evidence uncertainty** - a technician claim is not always sufficient proof of a critical requirement.
3. **Manual gap resolution** - someone must identify what is missing, find the owner, request it, and re-check the case.

2. Target customer

Initial beachhead

B2B HVAC / AC maintenance SMEs with recurring field jobs and an operations-to-finance handoff.

Primary user

Operations / admin coordinator responsible for ensuring completed jobs have sufficient documentation before billing.

Supporting users

- Field technician / supervisor
- Billing or finance admin
- Operations manager
- Customer approver

3. Existing alternatives

- Full Field Service Management platforms
- Accounting/ERP workflow after job completion
- WhatsApp / email + cloud drive + spreadsheet
- Manual admin review and technician follow-up

Existing FSM products already support forms, photos, customer signatures, closeout, approval, and invoicing. PROOF2PAY therefore **must not compete on basic data capture alone**.

4. Unique value proposition

Positioning

PROOF2PAY is an Evidence-to-Billing Intelligence Layer, not another FSM.

It is designed to answer:

- What was required?
- What evidence exists?
- Which claims are actually supported?
- What is blocking billing readiness?
- What is the smallest safe next action?

Memorable message

Finished != Billable

No proof -> no final billing-ready status for critical requirements.

5. Solution

AI Completion Intake

Converts technician notes and mixed evidence into structured facts, claims, and evidence candidates.

Requirement-to-Evidence Graph

Maps each job/SOW requirement to supporting evidence and preserves the source link.

Billing Readiness Engine

Returns explicit states such as **READY**, **MISSING**, **INCOMPLETE**, **AMBIGUOUS**, and **HUMAN_REVIEW**.

Gap-to-Action Agent

Plans the next step for each blocker and prepares follow-up actions. Consequential external actions require approval.

Completion Pack Generator

Produces a draft service/evidence package after critical blockers are resolved and a human confirms.

6. AI advantage

AI is central where rules alone struggle:

- interpreting short technician notes;
- extracting completion claims from unstructured text/documents;
- retrieving relevant requirements;
- matching heterogeneous evidence to requirements;
- explaining ambiguous or unsupported claims;
- planning follow-up actions and drafting completion narrative.

Deterministic logic remains responsible for critical blocker rules and valid state transitions.

7. Channels & go-to-market hypothesis

For a post-hackathon pilot:

1. Direct outreach to local technical-service SMEs.
2. Partner/integration motion with FSM/accounting implementers.
3. Free diagnostic pilot: measure completion-to-billing handoff and top missing evidence types.
4. SaaS conversion after value is measured.

This is a hypothesis; no channel economics have been validated yet.

8. Revenue model hypothesis

B2B SaaS with tiers based on active field team, completed jobs, integrations, and governance. Pricing and willingness-to-pay remain unvalidated.

9. Key metrics

For the hackathon, measure prototype outcomes rather than inventing market claims:

- time to identify missing evidence;
- critical blockers detected before billing handoff;
- time to prepare completion pack;
- task completion rate in synthetic test cases;
- percentage of readiness conclusions linked to source requirement and evidence;
- unsafe/ambiguous cases correctly routed to human review.

10. Unfair advantage - future, not claimed today

Potential long-term moat:

- vertical requirement/evidence templates;
- labeled resolution patterns;
- integration depth;
- customer-specific rules;
- historical blocker analytics;
- audit/governance layer.

These are roadmap possibilities, not current proprietary assets.

11. Validation status

Validated through secondary research: established FSM workflows contain completion forms, photos, customer signatures, approval stages, and invoicing handoffs. Indonesian official sources also document BAST as formal handover evidence in specific public-sector contexts.

Still unvalidated: prevalence, frequency, typical delay, willingness-to-pay, initial vertical superiority, and standalone-vs-add-on packaging.

12. Hackathon scope

In scope

- Synthetic W0-1028 HVAC scenario
- IBM Bob conversational orchestration
- MCP tool contract
- Langflow workflows
- controlled requirement source
- evidence mapping
- blocker explanation
- gap action planning
- human approval
- completion pack draft

Out of scope

- Dispatch/scheduling
- Full inventory system
- Accounting ledger
- Autonomous invoicing/payment
- Legal acceptance/signature authentication
- Production-grade fraud detection

13. Golden demo outcome

The demo should prove one statement:

PROOF2PAY can identify why a completed job is not yet billing-ready, help resolve the evidence gaps, and create a reviewable completion package without inventing evidence or bypassing human approval.
